## INTRODUCTION

The occurrence, extent, and preliminary geologic evaluation of coal beds in the Coleharbor quadrangle in west-central North Dakota are described in this report. minimal detailed data are available for this quadrangle, the geological mapping has been mostly dependent on knowledge of the regional geology as well as the geology of adjacent and surrounding quadrangles. In surrounding quadrangles, subsurface data consisting of oil and gas well and exploration drill hole logs and surface data comprised of measured sections were compiled for study and presentation. Federal coal ownership is presented on the Boundary and Coal Data Map, Plate A composite section of the projected geology of this quadrangle is shown on Coal Data Sheet, Plate 3. Derivative maps which consist of coal isopachs, structure contours, overburden, mining ratios, reserve categories, and Reserves and Reserve Base, have not been prepared for this quadrangle because of insufficient data.

This work has been performed under contract with the Conservation Division of the U.S. Geological Survey (Contract No. 14-08-0001-17118).

The resource information gathered in this program is in response to the Federal Coal Leasing Ammendments Acts of 1975

and is part of the U.S. Geological Survey's (USGS) coal program. The information is intended to provide basic data on coal resources for land-use planning purposes by the Bureau of Land Management, state and local governments, and the public.

#### LOCATION

The Coleharbor 7 1/2 minute quadrangle is located in McLean County, North Dakota about 6 miles (9.7 km) east of Riverdale and 8 miles (12.9 km) southeast of Garrison.

## ACCESSIBILITY

The area is accessible by State Highway 83 which connects with Interstate 94 at Bismarck, 54 miles (86.9 km) to the south.

The Soo Line Railroad operates and maintains a north-south route which extends through Garrison, Coleharbor and Underwood and passes through the quadrangle.

#### PHYSIOGRAPHY

The quadrangle lies in the central portion of a large topographic high known as the Missouri Plateau, which is being dissected by the Knife, Heart, Cannonball and Cedar Creek Rivers. In the eastern portion of the plateau the topography is generally hilly and along the Missouri River there are bluffs 500-600 feet (152-183 m) high. The western part of the Missouri Plateau is characterized by more irregular topography

than that which is prevalent throughout the remainder of the plateau. This area, known collectively as "the Badlands", comprises an intricate maze of narrow ravines, sharp crested ridges, and pinnacles.

The Coleharbor quadrangle may be characterized as gently rolling to hilly with a maximum relief across the quadrangle of 250 feet (76.2 m).

The vegetation is mixed prairie grasses and some of the land is cultivated.

## CLIMATE

North Dakota's climate may be characterized as semi-arid; the average annual precipitation is 18 inches (45.7 cm) at Washburn which is located 15.5 miles (24.9 km) southwest of the quadrangle.

Maximum precipitation occurs during the late spring and early summer with slightly over half the total annual precipitation occurring during May, June and July. Although the mean annual temperature is about 42°F (5.6°C), temperatures as recorded at the Washburn weather station by the U.S. Department of Commerce, can range from 103°F (39.4°C) in summer months to -22°F (-30.0°C) in winter months. The prevailing northerly winds increase in velocity during the colder months of November through March.

#### LAND STATUS

The quadrangle lies in the northern one-half of the Knife River Known Recoverable Coal Resources Area (KRCRA). The Federal Government owns the coal rights to approximately 10 percent of the quadrangle. In addition, the Federal Government has restricted coal rights on less than one percent of the area incorporated in the quadrangle.

## PREVIOUS WORK

This report has drawn on a number of basic data reports on the coal occurrences in the Knife River KRCRA, including: Law (1977), Benson (1953), and the United States Geological Survey (USGS) and North Dakota Geological Survey (NDGS) (1976, 1977). Ground water data reports in the Knife River area were also used, including: Croft (1970) and Klausing (1971, 1974, 1976).

## METHOD OF STUDY

Lithologic and geophysical logs from one drill hole and data from adjacent quadrangles provided the basic data for this study (Klausing, 1971). On the surrounding quadrangles, the quality of the available coal information is variable.

Lithologic and geophysical logs from exploration holes drilled by the North Dakota Geological Survey, North Dakota State Water Commission and private coal companies generally provide the most detailed and reliable subsurface data. Lithologic logs of

private water wells are less detailed and less reliable, but they provide usable information in many cases. Where the data for a specific coal bed appeared to be inaccurate or inconsistent, it was not included in the data base that was used for construction of derivative maps for that coal bed.

Drill hole data and projected coal outcrop traces from previous investigations (Law, 1977) were plotted on the coal data map, Plate 1.

## **GEOLOGY**

#### STRATIGRAPHY

The stratigraphy in the Coleharbor quadrangle is based on geologic data from Lake Nettie, and Underwood quadrangles. The oldest rocks present in the uppermost 500 feet (152.4 m) of stratigraphic section in the Coleharbor quadrangle is the coal-bearing Tongue River and Sentinel Butte members of the Fort Union Formation (Rehbein, 1977). Sandstones, siltstones and shales of this formation are locally mantled by erosional remnants of the Upper Paleocene-Lower Eocene Golden Valley Formation and by Quaternary glacial, eolian, and alluvial deposits.

# Fort Union Formation - Paleocene.

Tongue River member - this member ranges from 350 to 900 feet (107 to 274 m) thick and consists of an alternating

sequence of fluvially deposited sandstone, siltstone, shale, and lignite. It conformably overlies the marine Cannonball member and the time-equivalent, nonmarine Ludlow member. The Tongue River member is lithologically similar to the overlying Sentinel Butte member, and in places cannot be distinguished from it. The contact between the Tongue River and Sentinel Butte members, which has been arbitrarily set at the top of the HT Butte lignite, is conformable.

Sentinel Butte member - this member averages 500 feet (152 m) in thickness and consists of an alternating sequence of fluvially deposited sandstone, siltstone, shale, carbonaceous shale, and lignite. In general, the sandstones are fine grained and poorly cemented. Shales range from soft plastic near-clay to moderately indurated claystone. Locally, there are thin, calcareous or silicious concretions. Shale and siltstone zones readily break down and form gentle slopes beneath the sandstone ledges.

## Golden Valley Formation - Eocene.

This formation consists of about 200 feet (61 m) of alternating shales, siltstones, and crossbedded sandstones. These sediments which conformably overlie the Sentinel Butte member, have been eroded away in much of the study area.

# Channel Deposits - Pleistocene.

Sand and gravel channel deposits of indeterminate

thickness lie beneath early Wisconsinan glacial till and Quaternary alluvium in the area.

# Glacial Till - Pleistocene.

The glacial till is a heterogeneous mixture of clay, silt, sand, gravel, cobbles, and boulders which was deposited during Wisconsinan episodes of continental glaciation.

# Eolian Deposits - Pleistocene and Recent.

Unconsolidated dune and loess-like deposits from several inches to more than five feet thick, mantle most of the study area. The loess-like deposits consist of silty clays, clayey silt, and silty to clayey sands and are probably of late Pleistocene to Recent age. Recent dunes, consisting of silts and very fine grained uniform sand, have been deposited on the lee side of knobs and ridges.

## Alluvium - Recent.

Alluvium consisting of clay, silt, sand, and gravel mantles valley floors in the study area.

## STRUCTURE

Regionally the Knife River KRCRA is located on the southeastern flank of the Williston Basin, approximately 60 miles (97 km) from the basin center. Generally, the sedimentary units are flat lying or gently undulating, with a northward to northeastward regional dip ranging from less than 10 feet per mile (1.9 m per km) to 180 feet per mile (34 m per

km). Upper strata have been warped into a gentle syncline with a northeast to southwest trending axis located approximately 10 miles (16 km) east of the town of Dodge. The dips on the flanks of the syncline are approximately 18 feet per mile (3.4 m per km). Major faulting has not been observed in the area (Menge, 1977). Surficial materials generally mask most of the older stratigraphic units, making it difficult to assess the importance of minor faulting.

## DEPOSITIONAL ENVIRONMENTS OF THE LIGNITES

The Tongue River lignites are thick and laterally extensive. The HT Butte bed at the top of the Tongue River Formation can be traced over thousands of square miles. The lignite beds of the Tongue River member were formed in large swamps adjacent to fluvial channels (Rehbein, 1977).

The Sentinel Butte lignites, though fewer in number, are almost as continuous as the Tongue River lignites and had a similar depositional environment.

## COAL GEOLOGY

Three major coal beds and several local coal beds are either mapped at the surface or identified in the subsurface in quadrangles surrounding and adjacent to the Coleharbor quadrangle. Because of the laterally continuous nature of the

Knife River lignites, it is reasonable to expect their extension into this quadrangle. The Garner Creek coal bed is stratigraphically the lowest recognized coal bed. It is successively overlain by a rock interval approximately 250 feet (76.2 m) thick containing one local coal bed (Local 5, a local bed correlatable between several quadrangles); the Meyer coal bed; a rock interval approximately 55 feet (16.8 m) thick containing one local coal bed; and the HT Butte coal bed. The HT Butte coal bed is identified in the drill hole shown on Plates 1 and 3. This bed is less than 5 feet (1.5 m) thick and derivative maps were not prepared because of insufficient information. Table 1 shows the coal bed names and their stratigraphic position.

Drill hole data in the surrounding Lake Nettie quadrangle to the east indicates that the HT Butte coal bed is 2 feet (0.6 m) thick. In the Underwood quadrangle to the south, the HT Butte coal bed varies in thickness from 3 to 13 feet (0.9 to 4.0 m); and the Meyer coal bed varies in thickness from 2 to 11 feet (0.6 to 3.4 m). In the only drillhole on the Coleharbor quadrangle, the HT Butte coal bed is 4 feet (1.2 m) thick, and covered by approximately 27 feet (8.2 m) of overburden.

The coal beds of the Fort Union Formation in the Knife River KRCRA area are lignite in rank and contain 0.4 to 1.2 percent sulfur, less than 10 percent ash (Table A-1) and

Stratigraphic Equivalent

Hazen "A", Garrison Creek, Yeager, Hagel, Berg Keuther, Stanton between 5900 and 7300 BTU/lb. Coal analyses indicate that these coals have less than or about the same amount of trace elements as coal beds in other areas of the northern great plains coal province (Table A-2).

# COAL DEVELOPMENT POTENTIAL

Coal development potential for all mining methods (surface, subsurface and in situ gasification) in this quadrangle is rated unknown, because of insufficient data for their evaluation.
